

# micro-CLIMATES

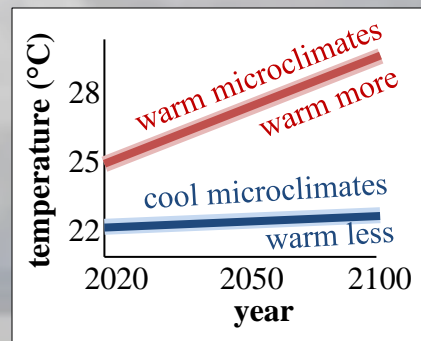

little locations with enormous value

## Species are vulnerable to warming, but...

16% of species have a high risk of extinction due to climate change. We are already seeing impacts on many species.

## locations that escape the heat...

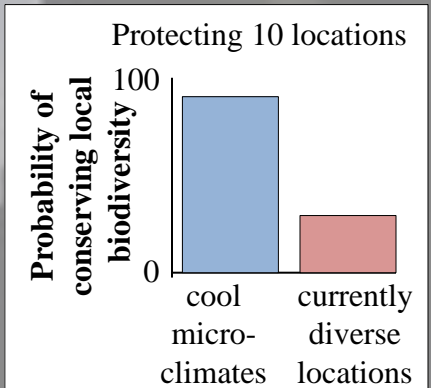

But, some small locations – microclimates – are warming less or staying cool despite warming.

## accumulate biodiversity...

Many species could congregate in cool microclimates to take refuge from the heat.

## providing conservation opportunities.

Protecting just a few cool microclimates might be an efficient means to conserve biodiversity in a warming world
